1. Centrifuge modelling:

Controlled normal/reverse faults (60° dip) in medium dense sand

Medium dense Fontainebleau sand.
($d_{50} = 0.2 \text{ mm}$; $C_u = 1.3$) $Dr \approx 60 \%$

Oil in/out raises/lowers block
→ fault displacement

- Accelerated to 115 g in centrifuge to produce same σ' as for 25 m soil depth.

- Allows well controlled and instrumented tests

2. Questions

- In which direction does the fault plane propagate through the soil in the free-field condition?

- How much fault offset, δ , causes fault rupture emergence?

- What happens when a footing is present?

- Dans quelle direction fait la propagation en état de champ libre?

- Combien de déplacement, δ , cause le rupture de faille pour émerger sur la surface de sol ?

- Que se produit avec une fondation?

3. Results: Free-field

Free-field normal fault

Profondeur de sol, $H = 25$ m;

Sable de Fontainebleau. Densité relative, $D_r = 60$ %;

$\delta=0$ m

Normal Fault: Free-field

Test 12_R2 (QUAKER) 01/04/2005: Dr=60% & $\theta=60$ deg.
Normal Fault in Free Field (Repeat Test 8 for Dr=60%)

$\delta=1.798$ m

Surface settlement profile

Profil de Tassement

Interaction with buildings/avec bâtiments??

- Problems for foundations/buildings even at small fault movements?

1:150 (0.4°): Structural damage of general buildings expected (Bjerrum, 1963)

4. Results: Fault-footing interaction

Heavy, rigid foundation

Fondation lourde et rigide

$B = 10 \text{ m}$; $q = 91 \text{ kPa}$

Sol:

$H = 25 \text{ m}$; Sable de Fontainebleau; $D_r = 60\%$

Foundation placed in the worst position?

Fondation placée dans la plus mauvaise position?

91 kPa

Free field fault

Test14_Repeat (Quaker) Bearing Foundation Pr. =90 kPa
Normal Fault-D_r=60% & Dip angle=60° 115g 29-03-2005

$\delta=0$ m

Test 14_R:
 $q = 91$ kPa, Normal fault

A photograph of a soil specimen, likely a sand, with alternating horizontal layers of light yellow and purple. A red dashed line indicates a fault line that runs diagonally from the top right towards the bottom center. The fault line shows a slight deviation to the left. A ruler is visible on the left side of the specimen, and another ruler is at the bottom. A white label with text is located at the bottom center. A red dashed line also extends from the bottom right corner towards the center.

**Fault deviates left
Little foundation rotation**

Test14_Repeat (Quaker) Bearing Foundation Pr. =90 kPa
Normal Fault-D_r=60% & Dip angle=60° 115g 29-03-2005

$\delta = 1.744 \text{ m}$

Foundation rotation

- Some foundation rotation at start of fault movement
- Rotation ceases once final mechanism is formed
- The structure may be OK

Lighter foundation

Fondation légère

$H = 25 \text{ m}$; Fontainebleau sand, $D_r = 60\%$
 $B = 10 \text{ m}$; **$q = 37 \text{ kPa}$**

Lighter footing

$H_f = 25 \text{ m}$

$\delta = 0$

Test 15 (QUAKER) 23-03-2005: $D=60\%$ & $\theta=60^\circ$
Normal Fault with Footing $P_r=35 \text{ kPa}$ (Repeat Test 9)

**Test 15: $q = 37 \text{ kPa}$,
Normal fault**

The photograph shows a soil specimen with alternating horizontal layers of light tan and dark purple material. A dashed red line indicates a fault line that runs diagonally from the top right towards the bottom center. Two red arrows point to the left along this fault line. A vertical ruler on the left side of the specimen shows a scale from 1 to 17 cm. A horizontal ruler at the bottom shows a scale from 5 to 21 cm. A small white label is placed on the bottom ruler. The specimen is held in a metal frame, and a red light is visible in the bottom right corner.

**Finally fault moves left
Little additional foundation
rotation**

$\delta=1.725$ m

Test 15 (QUAKER) 23-03-2005: D=60% & $\theta=60^\circ$
Normal Fault with Footing $P_r=35$ kPa (Repeat Test 9)

Foundation rotation

- More rotation with lighter footing

- Rotation θ is affected by q

- Significant rotation for lighter footing (despite identical final mechanism)

**Heavy foundation further away
from fault**

**Fondation lourde et plus loin de
la faille**

**Test 18_R: Normal fault, $q =$
91 kPa; offset by 5 m**

Fondation OK??

Free-field fault

Date: 14 / 10 / 05 Test 18_R
Foundation ($q=91\text{ kPa}$) with Normal
Fault 5m to left of centre-line
 H_{soil} : 25m, g-level: 115g, D_r : 60%

**Test 18_R: Normal fault, $q = 91\text{ kPa}$;
offset footing**

**Final mechanism
involves more
deviation of fault-
rupture**

Date: 14 / 10 / 05 Test 18_R
Foundation ($q=91\text{ kPa}$) with Normal
Fault 5^m to left of centre-line
 H_{soil} : 25^m, g-level: 115^g, D_r : 60[%]

$\delta = 3.68\text{ m}$

Rotation

- plus grande rotation!

5. Initial observations

- There are subtle soil-structure interaction effects
- Interaction depends on: Foundation position x , load q , breadth B , fault mode (normal/reverse and dip angle), foundation rigidity/strength?
- Fault deviation due to footings depends on a combination of:
 - (i) the changed stress field in the soil due to q ;
 - (ii) the additional work dissipated moving the foundation
 - (iii) the kinematic restraint of the footing.
- Even if the fault deviates away from the footing there may be significant foundation displacements associated with pre-failure mechanisms

The results may explain this behaviour in Golcuck:

– possible fault deviation

Photos/mapping from George Gazetas

Building 1 : 4 storeys + Basement – No Damage

The results may explain this behaviour in Golcuck:

- No fault deviation

Photo/mapping from George Gazetas

Building 2 : 1 storey – partial collapse

Méthode des éléments finis

et Studio Geotecnico Italiano, Milan

5. Conclusions

- Fault-footing interaction is a subtle soil-structure interaction problem
- Centrifuge modelling is a good tool for investigating this
- Further work is being done using finite element analysis and analytical methods to understand the problem and find critical conditions
- The findings will lead to design recommendations to be reported and disseminated next year
